

# Climate Change and Greenhouse Gas Reduction

## INTRODUCTION

Global warming is being recognized as a fact of life in most circles. Tangible evidence is accumulating on an almost daily basis—shorter winters, melting polar ice caps, rising sea levels, and deeper droughts. Greenhouse gasses are increasingly linked to global warming and are seen as the primary culprit.

Greenhouse gases are made up of carbon dioxide, methane, and nitrous oxides. They contribute to global warming by trapping radiation from the sun, blocking it from leaving earth's atmosphere and thereby increasing temperatures worldwide. The bulk of greenhouse gases emitted in the United States are associated with transportation (primarily cars and trucks) and energy generation and usage.

## IMPLICATIONS OF NOT ADDRESSING THE ISSUE

If current low-density, "sprawl" development patterns in many communities continues and expands, the ability to reduce Vehicle Miles Traveled (VMTs) in the future will be seriously impeded. Once development patterns are set, it is extremely difficult to affect travel patterns and preferences. Low-density development makes cost-effective mass transit nearly impossible.

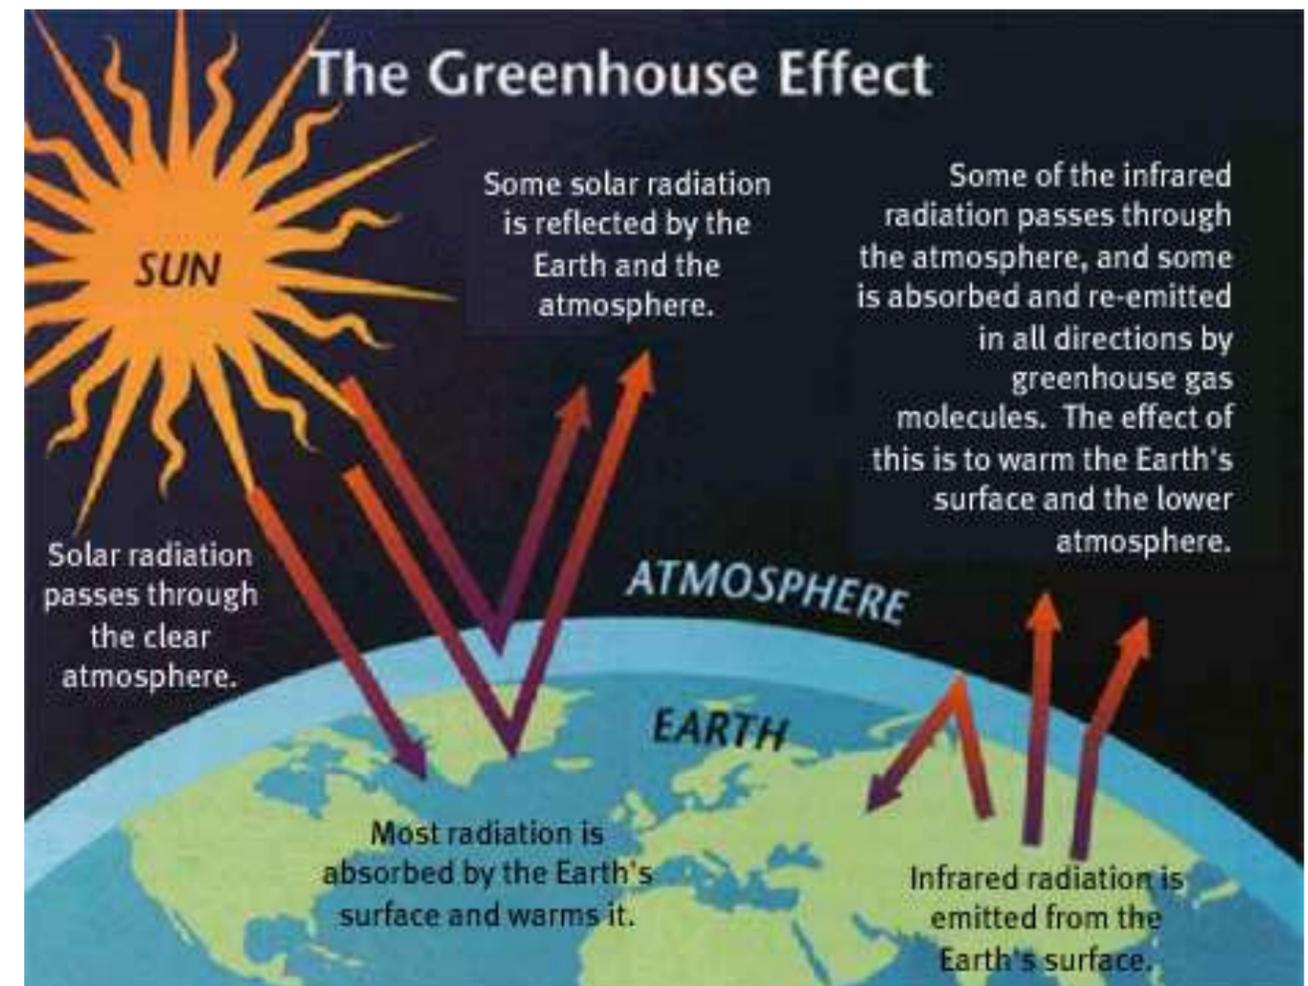

The same is true for preservation of mature trees that absorb huge quantities of greenhouse gases and sequester them for many years. If mature trees are needlessly cut to accommodate new development that excludes plans to preserve mature trees whenever possible, their destruction will actually release stored greenhouse gases through burning or rotting. It will take decades to replace them with smaller trees that absorb much less carbon dioxide in their early years.

Additionally, if communities do not take steps to accommodate and encourage alternative energy sources such as wind and solar, current development patterns may prohibit retrofitting in the future.

## THE ROLE OF LAND USE REGULATIONS IN CONTROLLING GREENHOUSE GAS GENERATION

Land use and zoning regulations can play an important role in helping to reduce greenhouse gas emissions through:

- Encouraging development patterns that allow less reliance on autos for mobility and result in reduction in vehicle miles traveled and corresponding greenhouse gas emissions
- Preserving existing trees that can sequester carbon dioxide, and require the planting of new trees
- Promoting alternative energy generation such as solar and wind power that do not generate greenhouse gases as do oil, gas, and coal-fired power plants

# Sustainable Community Development Code Framework

## CLIMATE CHANGE

### KEY STATISTICS AND FACTS:

- Greenhouse gases include carbon dioxide, methane, and nitrous oxides
- The United States, with 4% of the world's population, emits almost 25% of global carbon dioxide each year—second only to China. Carbon emissions in the U.S. have increased about 20% since 1990
- In the U.S., each person's direct emissions amount to 40% of this total—mostly from household energy and transportation. Total per person carbon emissions are about 16.5 metric tons (11.0 home; 5.00 auto; .5 air travel). 60% of transportation emissions come from fueling and driving autos
- The average mid-size car emits 9.500 pounds of carbon dioxide annually
- In the U.S., development is becoming more spread out—land consumed for development has increased at a rate of twice that of population growth between 1982 and 2002. During that period, per capita VMTs increased at three times the population growth
- According to a study of 83 metro areas by Reid Ewing, residents in compact regions (Boston, Portland) drove about 25% less than those in sprawling regions (Atlanta, Raleigh)
- Residents in the most walkable neighborhoods drive 26 fewer miles per day than those in the most sprawling areas according to a report conducted in King County, Washington, by Larry Frank. A study for the City of Sacramento, CA, reported that a compact growth scenario would result in a 25% reduction in VMT per house per day
- According to a study by Ewing, a doubling of development density can reduce VMTs by 5%. Other studies report a 5-15% reduction in VMTs associated with mixed-use projects
- According to the Dept. of Energy, a 30-year old hardwood tree can sequester the equivalent of 136 pounds of carbon dioxide annually. About 70 such trees would offset the carbon dioxide emissions from one medium-size car
- Planting a hectare of riparian forest can over the next 100 years offset the carbon emissions caused by 54,000 gallons of gasoline
- Net carbon sequestration by forests, urban trees, and agriculture can offset 15% of total U.S. carbon dioxide emissions annually
